- thermo- or quantum-chemically considered
8 Hydrogen - atomic, exotic and molecular ..... 6

## Notes - as a reminder

You have already received the information in the run-up to the competition, here are just a few keywords to remember:

- You are solely responsible for ensuring that we can match and read your answers.
- Show calculation methods when required.
- Do not forget the units.
- Use all digits of the molar masses and constants!
- For organic reaction schemes use the abbreviations (e.g., $\mathrm{MsCl}, \mathrm{tBu}, \ldots$...) which are also used in the specification

## Isomer counting by Alfred Werner and complexes of cobalt

Alfred Werner used the technique of isomer counting to deduce the structure of metal complexes with coordination number of six. Three of the shapes he considered are shown below.

In each structure, the empty circle shows the location of the central metal atom and the filled circles show the location of the ligands. Structure $\mathbf{X}$ is hexagonal planar, structure $\mathbf{Y}$ is trigonal prismatic and structure $\mathbf{Z}$ is octahedral.
For each of the three shapes, there is just one structure when all of the ligands are the same, i.e. when the complex has the general formula $\mathrm{MA}_{6}$ where A is the ligand. However, when achiral ligands A are substituted by one or more achiral ligands, it may be possible for each structure to form geometrical isomers. It might also be possible for one or more of the geometrical isomers to be optically active and exist as pairs of enantiomers.
The monodentate ligands A are substituted by monodentate ligands B or by symmetrical bidentate ligands, denoted C-C. Bidentate ligand C-C can only link between two atoms on adjacent positions, i.e. those positions connected by a line in the structures $\mathbf{X}, \mathbf{Y}$, and $\mathbf{Z}$.

> 1.1 In the answer sheet, create the table below. Indicate how many geometric isomers exist for each of the three structures $X$, $Y$, and $Z$. Write the number of possible geometric isomers in each box. If one of the isomers occurs as a pair of enantiomers, add an asterisk * to the number.

|  | number of predicted geometric isomers |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | hexagonal planar $\mathbf{X}$ |  | trigonal prismatic $Y$ |  | oktahedral Z |  |
| $\mathrm{MA}_{6}$ |  |  |  |  |  | 1 |
| $\mathrm{MA}_{4} \mathrm{~B}_{2}$ | 3 | 0,5 bp | 3* | 1 bp | 2 | 0,5 bp |
| $\mathrm{MA}_{4}(\mathrm{C}-\mathrm{C})$ | 1 | 0,5 bp | 2 | 0,5 bp | 1 | 0,5 bp |
| $\mathrm{MA}_{2}(\mathrm{C}-\mathrm{C})_{2}$ | 2 | 0,5 bp | 4* | 1 bp | 3* | 1 bp |

## 6 bp

There are no known complexes that adopt the hexagonal planar geometry $\mathbf{X}$, but structures are known for both the trigonal prismatic geometry $\mathbf{Y}$ and the octahedral geometry $\mathbf{Z}$. In these complexes, the orbitals derived from the metal d-orbitals have different energies depending on the geometry of the complex. The splitting patterns for the trigonal prismatic geometry and for the octahedral geometry are shown below.

1.2 Draw the energy level diagram for both coordinations/shapes and label which $d$ orbitals are which.

The complexes $\left[\mathrm{Mn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ and $\left[\mathrm{Mn}(\mathrm{CN})_{6}\right]^{2-}$ are both octahedral. One has a magnetic moment of $5,9 \mu_{B}$, the other has a magnetic moment of $3,9 \mu_{\mathrm{B}}$.
1.3 Draw an occupancy scheme for the d-orbitals for both complexes and write the appropriate magnetic moment.

Octahedral complexes are far more common than trigonal prismatic. Werner isolated five compounds C, D, E, F, G containing $\mathrm{Co}(\mathrm{III}), \mathrm{Cl}$, and $\mathrm{NH}_{3}$ only, each of which contained one octahedral complex. Werner's five compounds had the molar conductivities shown below. The conductivities are extrapolated to infinite dilution and are expressed in arbitrary units. Compound $G$ does not react with aqueous $\mathrm{AgNO}_{3}$; compounds $\mathrm{C}, \mathrm{D}$, and E react with different stoichiometric ratios of aqueous $\mathrm{AgNO}_{3} ; \mathrm{E}$ and F react with the same stoichiometric ratio of aqueous $\mathrm{AgNO}_{3}$.

|  | C | D | E | F | G |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Molar conductivity <br> in S cm ${ }^{2}$ mol $^{-1}$ | 510 | 372 | 249 | 249 | $\sim 0$ |

### 1.4 Draw all possible structures of compounds $C, D, E, F, G$.

Here is a three-dimensional model of another octahedral complex of cobalt with different ligands ( N is purple, H is white, O is red).

### 1.5 Enter the IUPAC name, including the stereo descriptor of the cobalt(III) complex. trans-Tetraammindinitrocobalt(III)-Kation

Many complexes exist as isomers, with a distinction being made between stereo and structural isomers.

| 1.6 | Give the formula for an ionization isomer of $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5}\left(\mathrm{NO}_{3}\right)\right] \mathrm{SO}_{4}$. |
| :--- | :--- | :--- |
| $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5}\left(\mathrm{SO}_{4}\right)\right] \mathrm{NO}_{3}$ | $\mathbf{0 , 5} \mathbf{~ b p}$ |

Cobalt(III) complexes are octahedral and intensely colored. Three complex compounds with ligand field splitting are listed in the table. The possible colors are yellow, orange-yellow, blue, and dark green.

|  | Complex | Ligand field <br> splitting in $\mathrm{cm}^{-1}$ |
| :---: | :---: | :---: |
| (i) | $\left[\mathrm{Co}\left(\mathrm{C}_{2} \mathrm{O}_{4}\right)_{6}\right]^{3-}$ | 18000 |
| (ii) | $\left[\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$ | 18200 |
| (iii) | $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$ | 22900 |
| (iv) | $\left[\mathrm{Co}(\mathrm{en})_{3}\right]^{3-}$ | 33500 |

1.7 Assign the correct color to each complex (e.g., write (vii) green).

Cobalt does not form only complex compounds. The olive green cobalt(II) oxide is formed from the elements at $1100^{\circ} \mathrm{C}$. The ionic radius of $\mathrm{Co}^{2+}$ is $0,82 \AA$ and that of the oxide ion is 140 pm .
1.8 In which type (CsCl, NaCl, ZnS) does cobalt(II) oxide crystallize? Prove your claim with a calculation.

$$
\begin{gathered}
\frac{r_{\text {Kation }}}{r_{\text {Anion }}}=\frac{0,82 \cdot 10^{-10}}{140 \cdot 10^{-12}}=0,58 \\
0,41<0,58<0,73 \rightarrow \text { NaCl Type }
\end{gathered}
$$

$1,5 \mathrm{bp}$
Another cobalt compound is Thénards Blau. That compound, also called cobalt blue ( $M=$ $176.89 \mathrm{~g} / \mathrm{mol}$ ), has a spinel structure shown below:

A and B are two different metal ions with different oxidation numbers that coordinate tetrahedrally and octahedrally with $\mathrm{O}^{2-}$ ions. In fact, tetrahedrally coordinated sites are often called A sites, and octahedrally coordinated sites are called B sites. The figure on the left introduces the unit cell of spinel. The right one shows the inner workings of the 8 cube parts, so to speak, and thus indicates exactly where which atoms are located. The four rear cubes are not filled in for clarity, but of course, they are occupied as well as the front ones.

### 1.9 Determine the formula of the unit cell and the empirical formula for compounds with spinel structure.

A: $8 \cdot \frac{1}{8}+6 \cdot \frac{1}{2}=4 \rightarrow \mathrm{~A}_{4}$
additional 4 places A , so $\mathrm{A}_{1} \mathrm{O}_{4} \rightarrow \mathrm{~A}_{4} \mathrm{O}_{16}$
4 places B , so $\mathrm{B}_{4} \mathrm{O}_{4} \rightarrow \mathrm{~B}_{16} \mathrm{O}_{16}$
formula of the unit cell: $\mathrm{A}_{8} \mathrm{~B}_{16} \mathrm{O}_{32}$
empirical formula: $\mathrm{AB}_{2} \mathrm{O}_{4}$

$$
\begin{aligned}
& \text { 1.10 Determine the molecular formula of Thénards Blue. } \\
& \mathrm{M}_{( }\left(\mathrm{AB}_{2} \mathrm{O}_{4}\right)=176,89 \mathrm{~g} / \mathrm{mol}
\end{aligned}
$$

$\mathrm{M}\left(\mathrm{AB}_{2}\right)=176,89-16 \cdot 4=112,89 \mathrm{~g} / \mathrm{mol}$
assume $B=C o \rightarrow M(A)=112,89-2 \cdot 58,93=-4,97 \mathrm{~g} / \mathrm{mol} \longrightarrow$ not possible
assume $A=C o \longrightarrow M\left(B_{2}\right)=112,89-58,93=53,96 \mathrm{~g} / \mathrm{mol} \longrightarrow 2 \mathrm{Al}$
$\mathrm{CoAl}_{2} \mathrm{O}_{4}$

Cobalt compounds are used in medicine to treat cyanide poisoning. The person poisoned with cyanide receives an infusion with a solution of a chelate complex consisting of cobalt(II) and the hexavalent ligand (EDTA) ${ }^{4}$. In a ligand exchange reaction, the cyanide ions present in the blood form very stable hexacyanidocobalt(II) complex, which is easily soluble in water and excretable.

| 1.11 Give a coordinated ion equation of the ligand exchange reaction. |  |
| :---: | :---: |
| $[\mathrm{Co}(\mathrm{EDTA})]^{2-}+6 \mathrm{CN} \rightarrow\left[\mathrm{Co}(\mathrm{CN})_{6}\right]^{4-}+\mathrm{EDTA}^{4-}$ | $\mathbf{0 , 5} \mathbf{~ b p}$ |

Another medical application is the nuclide cobalt-60 as a powerful gamma radiation source for irradiating malignant tumors when other forms of therapy fail. Cobalt-60 is exclusively obtained artificially by neutron activation from the only stable cobalt- 59 nuclide and shows $\beta$ - decay.
1.12 Write down the two nuclear reaction equations for the formation and decay of cobalt-
60 .

| 59 |  |
| :--- | :--- |
| ${ }_{27} \mathrm{Co}$ | $+{ }_{0}^{1} n \rightarrow{ }_{27}^{60} \mathrm{Co}$ |
| ${ }_{27}^{60} \mathrm{Co} \rightarrow{ }_{28}^{60} \mathrm{Ni}+{ }_{-1}^{0} e+\overline{v_{e}}$ | $\mathbf{1 ~ b p}$ |

Elemental cobalt is steel grey, shiny, and harder than iron. It crystallizes in the modifications: $450^{\circ} \mathrm{C}$

$$
\alpha-\mathrm{Co} \rightleftharpoons \beta-\mathrm{Co}
$$

While $\alpha$-Co has a hexagonal-dense crystal structure, the structure of $\beta$-Co is face-centered cubic (fcc). The metal radius of cobalt is $1,25 \AA$.

| 1.13 Calculate the density of $\beta$-Co in $\mathrm{g} / \mathrm{cm}^{3}$. |  |
| :--- | :--- |
| $2 a^{2}=\left(4 \cdot 1,25 \cdot 10^{-8}\right)^{2} \Rightarrow a \approx 3,5355 \cdot 10^{-8} \mathrm{~cm}$ |  |
| 4 atoms $/ \mathrm{uc}(\mathrm{fcc})$ | $\mathbf{1 , 5} \mathbf{~ b p}$ |
| $\rho=\frac{4 \cdot 58,93}{6,0221 \cdot 10^{23} \cdot\left(3,5355 \cdot 10^{-8}\right)^{3}}=8,857 \mathrm{~g} / \mathrm{cm}^{3}$ | $\mathbf{1}$ |

## Chlorine in the pool and equilibrium

Inexpensive frame pools are being sold more and more frequently in Austria. Such a frame pool was purchased to offer the teachers a balance to their hard work. This pool has a capacity of $17,00 \mathrm{~m}^{3}$. It was completely filled up with tap water and now has a temperature of $25^{\circ} \mathrm{C}$. For further calculations, it can be assumed that the tap water initially contained no dissolved salts.
Then $50,00 \mathrm{~kg}$ of NaCl were added to the water in the pool and dissolved. A so-called "salt plant" is responsible for the disinfection of the pool water. Here the pool water is subjected to electrolysis, using a current of $3,79 \mathrm{~A}$. Chlorine gas is produced at the anode and hydrogen at the cathode.
2.1 Calculate the concentration of chloride ions in the pool water before the electrolysis.
$n=\frac{m}{M}=\frac{50000 \mathrm{~g}}{58,44 \mathrm{~g} \cdot \mathrm{~mol}^{-1}}=855,58 \mathrm{~mol}$
$c=\frac{n}{V}=\frac{855,58 \mathrm{~mol}}{17000 \mathrm{~L}}=0,0503 \mathrm{~mol} / \mathrm{L}$

| 2.2 | Write the reaction equations for the cathodic and anodic processes. |  |
| :--- | :--- | :--- |
| cat: $2 \mathrm{H}_{2} \mathrm{O}+2 \mathrm{e}^{-} \rightleftharpoons \mathrm{H}_{2}+2 \mathrm{OH}^{-}$ |  |  |
| an: $2 \mathrm{Cl}^{-} \rightleftharpoons \mathrm{Cl}_{2}+2 \mathrm{e}^{-}$ | $\mathbf{1 ~ b p}$ |  |

| 2.3 | Calculate the mass of chlorine gas produced per hour, assuming a complete electric <br> yield. |
| :--- | :--- |
| $m=\frac{M \cdot I \cdot t}{z \cdot F}=\frac{70,90 \cdot 3,79 \cdot 3600}{2 \cdot 96485}=5,01 \mathrm{~g}$ | $\mathbf{1} \mathbf{~ b p}$ |

2.4 Calculate the pH value of the pool if electrolysis was conducted for 10 hours and assuming that only the hydroxide ions formed at the cathode influence this pH value.
$n\left(\mathrm{OH}^{-}\right)=2 \frac{I \cdot t}{z \cdot F}=2 \frac{3,79 \cdot 36000}{2 \cdot 96485}=1,414 \mathrm{~mol}$
$c\left(\mathrm{OH}^{-}\right)=\frac{n}{V}=\frac{1,414 \mathrm{~mol}}{17000 \mathrm{~L}}=8,32 \cdot 10^{-5} \mathrm{~mol} / \mathrm{L}$
$\mathrm{pH}=14+\log \left(8,32 \cdot 10^{-5}\right)=9,92$

For further calculations, assume that in the pool mentioned above with a volume of $17,00 \mathrm{~m}^{3}$ after the addition of $50,00 \mathrm{~kg}$ of NaCl and several days of electrolysis, a total of $60,0 \mathrm{~g}$ of chlorine gas has dissolved in the water of the pool and that the pool contents has a stable pH of 9,50 and that none of the reactions taking place have a significant influence on the concentration of dissolved chloride ions or the pH value. The chlorine gas reacts with water according to the following equation:

$$
\mathrm{Cl}_{2(\mathrm{aq})}+2 \mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{HOCl}+\mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{Cl}^{-} \quad K=4,20 \cdot 10^{-4}
$$

As is common practice with reaction constants, the concentration of water is set to 1 for this constant. The hypochlorous acid HOCl formed is a weak acid with a $\mathrm{pK}_{\mathrm{a}}$ value of 7,54 .
2.5 To determine which chlorine-containing oxidant plays the most significant role in preventing contamination of the pool, calculate the concentrations of dissolved chlorine gas, hypochlorous acid, and hypochlorite anion in equilibrium under the given conditions.
$n_{0}\left(C l_{2}\right)=\frac{60 \mathrm{~g}}{70,9 \mathrm{~g} \cdot \mathrm{~mol}^{-1}}=0,846 \mathrm{~mol} \Rightarrow c_{0}\left(C l_{2}\right)=\frac{0,846 \mathrm{~mol}}{17000 \mathrm{~L}}=4,98 \cdot 10^{-5} \mathrm{~mol} / \mathrm{L}$
$\left[\mathrm{Cl}^{-}\right]=0,0503 \mathrm{~mol} / \mathrm{L}$ and $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=10^{-9,50} \mathrm{~mol} / \mathrm{L}$
abbreviations $\quad\left[\mathrm{Cl}_{2}\right]=g \quad[\mathrm{HOCl}]=s \quad\left[\mathrm{OCl}^{-}\right]=a$
(I) $\quad K=\frac{[\mathrm{HOCl}] \cdot\left[\mathrm{H}_{3} \mathrm{O}^{+}\right] \cdot[\mathrm{Cl}-]}{\left[\mathrm{Cl} l_{2}\right]}=\frac{s \cdot 10^{-9,50 \cdot 0,0503}}{g}=4,20 \cdot 10^{-4}$
(II) $\quad K_{A}=\frac{\left[\mathrm{OCl}^{-}\right] \cdot\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]}{[\mathrm{HOCl}]}=\frac{a \cdot 10^{-9,50}}{s}=10^{-7,54}$
(III) $\quad c_{0}\left(\mathrm{Cl}_{2}\right)=\left[\mathrm{Cl}_{2}\right]+[\mathrm{HOCl}]+\left[\mathrm{OCl}^{-}\right]=g+s+a=4,98 \cdot 10^{-5} \mathrm{~mol} / \mathrm{L}$
(I) $\quad g=\frac{s \cdot 10^{-9,50} \cdot 0,0503}{4,20 \cdot 10^{-4}}=s \cdot 3,79 \cdot 10^{-8}$
(II) $\quad a=\frac{\left(10^{-7,54} \cdot s\right)}{10^{-9,50}}=91,2 \cdot s$
(III) $s \cdot 3,79 \cdot 10^{-8}+s+91,2 \cdot s=4,98 \cdot 10^{-5} \quad \Rightarrow s=5,40 \cdot 10^{-7}$
$[\mathrm{HOCl}]=5,40 \cdot 10^{-7} \mathrm{~mol} / \mathrm{L}$
$\left[\mathrm{Cl}_{2}\right]=5,40 \cdot 10^{-7} \cdot 3,79 \cdot 10^{-8}=2,05 \cdot 10^{-14} \mathrm{~mol} / \mathrm{L}$
$\left[\mathrm{ClO}^{-}\right]=91,2 \cdot 5,40 \cdot 10^{-7}=4,92 \cdot 10^{-5} \mathrm{~mol} / \mathrm{L}$

In the previous example, it was assumed that the pH value does not change during the reactions taking place. The actual change should now be determined. For simplification, we now assume that the entire $60,0 \mathrm{~g}$ chlorine gas is first converted into hypochlorous acid. The pH value before the introduction of the chlorine gas is again 9,50.
2.6 Calculate the pH value in the pool by taking into account the $\mathrm{H}_{3} \mathrm{O}^{+}$ions formed during the hydrolysis of the chlorine gas. Neglect the acid effect of the (weak) hypochlorous acid.
$n_{0}\left(\mathrm{Cl}_{2}\right)=\frac{60 \mathrm{~g}}{70,9 \mathrm{~g} \cdot \mathrm{~mol}^{-1}}=0,846 \mathrm{~mol}=n_{\text {glgw }}(\mathrm{HClO})=n_{\text {gebildet }}\left(\mathrm{H}_{3} \mathrm{O}^{+}\right)$
$n_{0}\left(\mathrm{OH}^{-}\right)=10^{-4,50} \cdot 17000=0,538 \mathrm{~mol}$
$\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=\frac{0,846-0,538}{17000}=1,812 \cdot 10^{-5} \mathrm{~mol} / \mathrm{L}$
$p H=-\log \left(1,812 \cdot 10^{-5}\right)=4,74$

## Problem 3 (C. Hurban)

## Electrochemistry of some chlorine compounds

Various chlorine compounds are still used as disinfectants.
Incomplete Latimer diagrams for chlorine are given at $\mathrm{pH}=0$ and $\mathrm{pH}=14$. All potentials are given in Volts.

$$
\begin{aligned}
& \mathrm{pH}=0: \quad \mathrm{ClO}_{3}^{-} \xrightarrow{+1,428} \mathrm{HClO} \xrightarrow{+1,630} \mathrm{Cl}_{2} \xrightarrow{+1,358} \mathrm{Cl}^{-} \\
& \mathrm{pH}=14: \quad \mathrm{ClO}_{3}^{-} \xrightarrow{+0,488} \mathrm{HClO} \xrightarrow{+0,421} \mathrm{Cl}_{2} \xrightarrow{+1,358} \mathrm{Cl}^{-}
\end{aligned}
$$

3.1 Calculate the standard potentials of the chlorate/chlorine redox pair at $\mathrm{pH}=0$ and $p H=14$.
at $\mathrm{pH}=0: \quad E^{O}=\frac{4 \cdot 1,428+1,630}{5}=1,468 \mathrm{~V}$
at $\mathrm{pH}=14: \quad E^{O}=\frac{4 \cdot 0,488+0,421}{5}=0,475 \mathrm{~V} \quad 2 \mathbf{b p}$
3.2 Write down the half equations for the redox pairs chlorate/chlorine and chlorine/chloride at $\mathrm{pH}=0$.
$\mathrm{ClO}_{3}{ }^{-}+5 \mathrm{e}^{-}+6 \mathrm{H}^{+} \rightarrow 0,5 \mathrm{Cl}_{2}+3 \mathrm{H}_{2} \mathrm{O} \quad 1 \boldsymbol{b p}$
$\mathrm{Cl}_{2}+2 \mathrm{e}^{-} \rightarrow 2 \mathrm{Cl}^{-}$
3.3 For both redox pairs from 3.2, enter mathematical expressions for the potential that make it clear why those two redox pairs behave differently at different pH values.
$E=E^{O}-\frac{R T}{5 F} \ln \frac{\left[C l_{2}\right]^{0,5}}{\left[C O_{3}^{-}\right]\left[H^{+}\right]^{6}} \quad E=E^{O}-\frac{R T}{2 F} \ln \frac{\left[\mathrm{Cl}^{-}\right]^{2}}{\left[\mathrm{Cl}_{2}\right]}$
In the half equation of chlorate there are $\mathrm{H}^{+}$, therefore the $\mathrm{H}^{+}$-concentration is in the Nernst equation, therefore dependant on the pH .
In the second half equation this is not the case. $\mathbf{2} \mathbf{~ b p}$

|  | Draw a Frost diagram for the chlorine compounds at $\mathrm{pH}=0$ and $\mathrm{pH}=14$ in the same diagram. |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | (Cl(5)/Cl(0)) | (Cl(1)/Cl(0)) | $(\mathrm{Cl}(0) / \mathrm{Cl}(0))$ | $(\mathrm{ClI}(-1) / \mathrm{Cl}(0))$ |
|  | N | 5 | 1 | 0 | -1 |
|  | n | 5 | 1 | 0 | 1 |
|  | $E^{O}(\mathrm{pH}=0)$ | 1,468 | 1,630 | 0 | -1,358 |
|  | $n E^{O}(\mathrm{pH}=0)$ | 7,340 | 1,630 | 0 | -1,358 |
|  | $E^{O}(\mathrm{pH}=14)$ | 0,475 | 0,421 | 0 | -1,358 |
|  | $n E^{O}(\mathrm{pH}=14)$ | 2,375 | 0,421 | 0 | -1,358 |

3.5 Specify whether $\mathrm{Cl}_{2}$ in acids $(\mathrm{pH}=0)$ or bases $(\mathrm{pH}=14)$ tends to disproportionate to $\mathrm{ClO}^{-}$and $\mathrm{Cl}^{-}$. (yes/no) Justify your respective decision with the help of the frost diagram and/or data from the Latimer diagram.
$\mathrm{Cl}_{2}$ does not disproportionate under acidic conditions because
$E^{\mathrm{O}}(\mathrm{Cl}(\mathrm{I}) \mid \mathrm{Cl}(0))=1,630>E^{\mathrm{O}}(\mathrm{Cl}(0) \mid \mathrm{Cl}(-\mathrm{I}))=1,358$, or
the point of $\mathrm{Cl}_{2}$ lies below the line connecting the neighboring points. $\mathrm{Cl}_{2}$
disproportionates under basic conditions because
$E^{O}(\mathrm{Cl}(\mathrm{I}) \mid \mathrm{Cl}(0))=0,421<E^{O}(\mathrm{Cl}(0) \mid \mathrm{Cl}(-\mathrm{I}))=1,358$ or
The point of $\mathrm{Cl}_{2}$ above the line connecting the neighboring points.
$1,5 \mathrm{bp}$
3.6 Calculate the potential of the half cell chlorate/chlorine at $T=298 \mathrm{~K}$, bringing the pH to 7.0 and not changing the other concentrations.

Für: $\mathrm{ClO}_{3}{ }^{-}+5 \mathrm{e}^{-}+6 \mathrm{H}^{+} \rightarrow 0,5 \mathrm{Cl}_{2}+3 \mathrm{H}_{2} \mathrm{O}$
$E=E^{O}-\frac{R T}{z F} \ln \frac{\left[C l_{2}\right]^{0,5}}{\left[C l O_{3}^{-}\right]\left[H^{+}\right]^{6}}=1,468-\frac{8,314 \cdot 298}{5 \cdot 96485} \ln \left(10^{-7}\right)^{-6}=0,971 \mathrm{~V}$ $1,5 \mathrm{bp}$

## Problem 4 (C. Hurban)

## Kinetics of air pollution

## A. Formation of NO

The one-step reaction, according to the following equation, plays a major role in the field of air pollution:

$$
2 \mathrm{NO}_{2}(\mathrm{~g}) \rightarrow 2 \mathrm{NO}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g})
$$

### 4.1 Express the reaction rate with respect to partial pressures of all three species.

 $v=-\frac{1}{2} \frac{d p\left(N O_{2}\right)}{d t}=\frac{1}{2} \frac{d p(N O)}{d t}=\frac{d p\left(O_{2}\right)}{d t}$In the left figure, the partial pressures of three species are plotted against time; the right figure shows a curve for the starting material.

If $\mathrm{NO}_{2}$ is filled into a container of $2,0 \mathrm{~L}$ with an initial pressure of 0,80 bar and $600^{\circ} \mathrm{C}, 50 \%$ of the $\mathrm{NO}_{2}$ is converted after 3,0 minutes.

[^0]$$
k=\frac{1}{\tau \cdot p_{0}\left(\mathrm{NO}_{2}\right)}=\frac{1}{180 \cdot 0,8}=6,9 \cdot 10^{-3} \mathrm{~s}^{-1} \cdot \mathrm{bar}^{-1} \quad 1 \mathrm{bp}
$$

## B. Formation of $\mathrm{NO}_{2}$

The reaction in the other direction is more important at low temperatures:

$$
2 \mathrm{NO}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \rightarrow 2 \mathrm{NO}_{2}(\mathrm{~g})
$$

The following rate law was found for them:

$$
v=k \cdot c(\mathrm{NO})^{2} c\left(\mathrm{O}_{2}\right)
$$

4.7 Specify how the reaction rate changes when the following changes in concentration are made. (For example, write "(vi): v increases by a factor of 4")
i) $c\left(\mathrm{O}_{2}\right)$ is quadrupled,
ii) $c(\mathrm{NO})$ is quadrupled,
iii) $c(\mathrm{NO})$ is halved,
iv) $c\left(\mathrm{O}_{2}\right)$ is halved, and $c(\mathrm{NO})$ is quadrupled,
v) $c(\mathrm{NO})$ is halved, and $c\left(\mathrm{O}_{2}\right)$ is quadrupled.

| (i) | v increases by a factor of 4, |  |
| :--- | :--- | :--- |
| (ii) | v increases by a factor of 16, |  |
| (iii) | v decreases by a factor of $1 / 4$, |  |
| (iv) | v increases by a factor of 8, | $\mathbf{2 , 5} \mathbf{~ b p}$ |
| (v) | v does not change |  |

The initial velocity of the considered reaction remains constant if the temperature is increased from $460^{\circ} \mathrm{C}$ to $600^{\circ} \mathrm{C}$, and all initial concentrations are bisected.
4.8 Calculate the activation energy.
When the initial concentrations are bisected the velocity of the reaction is cut to $1 / 8$. So
considering the velocity stays the same by increasing the temperature $k$ has to increase
by a factor of 8 .

$k=A \cdot e^{-\frac{E_{a}}{R \cdot T} \quad \ln k=\ln A-\frac{E_{a}}{R \cdot T}}$| $E_{a}=-R \cdot \ln \frac{k_{2}}{k_{1}} \cdot\left(\frac{1}{T_{2}}-\frac{1}{T_{1}}\right)^{-1}=-8,314 \cdot \ln 8 \cdot\left(\frac{1}{873,15}-\frac{1}{733,15}\right)^{-1}$ |
| :--- |
| $E_{\mathrm{a}} \approx 79 \mathrm{~kJ} / \mathrm{mol}$ |$\quad \mathbf{2 , 5 \mathbf { b p }}$

## C. Radicals

The radical OH plays a vital role in the chemistry of the atmosphere. It is very unstable and short-lived. Since it reacts with many air pollutants (such as methane and ozone) and often acts as the first step in their removal, it is sometimes referred to as the "cleaning agent of the troposphere".
It can also react with $\mathrm{O}_{2}$, producing the radical $\mathrm{HO}_{3}$. The reaction between $\mathrm{O}_{2}$ and OH has been studied in detail, and the following mechanism for the formation of $\mathrm{HO}_{3}$ has been proposed:

$$
\begin{gathered}
\mathrm{OH}+\mathrm{O}_{2} \xrightarrow{k_{1}} \mathrm{HO}_{3}{ }^{*} \\
\mathrm{HO}_{3}{ }^{*} \xrightarrow{k_{2}} \mathrm{OH}+\mathrm{O}_{2} \\
\mathrm{HO}_{3}{ }^{*}+\mathrm{N}_{2} \xrightarrow{k_{3}} \mathrm{HO}_{3}+\mathrm{N}_{2}
\end{gathered}
$$

$\mathrm{HO}_{3}{ }^{*}$ represents an excited state of $\mathrm{HO}_{3}$. For the following calculations, consider $\mathrm{HO}_{3}{ }^{*}$ and $\mathrm{HO}_{3}$ as two different chemical compounds.
4.9 Give the rate law for each elementary reaction.
$\mathrm{v}_{1}=\mathrm{k}_{1} \cdot[\mathrm{OH}] \cdot\left[\mathrm{O}_{2}\right]$

$$
\begin{aligned}
\mathrm{v}_{2} & =\mathrm{k}_{2} \cdot\left[\mathrm{HO}_{3}{ }^{*}\right] \\
\mathrm{v}_{3} & =\mathrm{k}_{3} \cdot\left[\mathrm{HO}_{3}{ }^{*}\right] \cdot\left[\mathrm{N}_{2}\right]
\end{aligned}
$$

4.10 Derive an equation for the rate of formation of $\mathrm{HO}_{3}$. Use the steady-state approximation for all intermediate products.
$v=\frac{d\left[\mathrm{HO}_{3}\right]}{d t}=k_{3} \cdot\left[\mathrm{HO}_{3}{ }^{*}\right] \cdot\left[\mathrm{N}_{2}\right]$
$\frac{d\left[\mathrm{HO}_{3}{ }^{*}\right]}{d t}=k_{1} \cdot[\mathrm{OH}] \cdot\left[\mathrm{O}_{2}\right]-k_{2} \cdot\left[\mathrm{HO}_{3}{ }^{*}\right]-k_{3} \cdot\left[\mathrm{HO}_{3}{ }^{*}\right] \cdot\left[\mathrm{N}_{2}\right]=0 \Rightarrow$

$$
k_{1} \cdot[\mathrm{OH}] \cdot\left[\mathrm{O}_{2}\right]=\left[\mathrm{HO}_{3}^{*}\right] \cdot\left(k_{2}+k_{3} \cdot\left[\mathrm{~N}_{2}\right]\right) \Rightarrow
$$

$$
\left[\mathrm{HO}_{3}{ }^{*}\right]=\frac{k_{1} \cdot[\mathrm{OH}] \cdot\left[\mathrm{O}_{2}\right]}{k_{2}+k_{3} \cdot\left[\mathrm{~N}_{2}\right]}
$$

$v=\frac{d\left[\mathrm{HO}_{3}\right]}{d t}=k_{3} \cdot\left[\mathrm{HO}_{3}{ }^{*}\right] \cdot\left[\mathrm{N}_{2}\right]=\frac{k_{1} \cdot k_{3} \cdot[\mathrm{OH}] \cdot\left[\mathrm{O}_{2}\right] \cdot\left[\mathrm{N}_{2}\right]}{k_{2}+k_{3} \cdot\left[N_{2}\right]}$
$3,5 \mathrm{bp}$
4.11 The expression obtained in 4.10 becomes more straightforward if we assume that $k_{2}$ is negligibly small. What is the simplified expression?
$v=\frac{k_{1} \cdot k_{3} \cdot[\mathrm{OH}] \cdot\left[\mathrm{O}_{2}\right] \cdot\left[\mathrm{N}_{2}\right]}{k_{2}+k_{3} \cdot\left[N_{2}\right]} \approx \frac{k_{1} \cdot k_{3} \cdot[\mathrm{OH}] \cdot\left[\mathrm{O}_{2}\right] \cdot\left[\mathrm{N}_{2}\right]}{k_{3} \cdot\left[N_{2}\right]}=k_{1} \cdot[\mathrm{OH}] \cdot\left[\mathrm{O}_{2}\right]$

## Problem 5 (M. Scherl)

## Organic synthesis

## A. Synthesis of conicein <br> (15 bp)

(Jung, M.E.; Choi, Y.M. J. Org. Chem. 1991, 56, 6729.)
This problem is about the synthesis of conicein, a heterocyclic alkaloid. In 1991 it was manufactured using elegant pericyclic reaction steps.

| 5.1 | Dr |
| :---: | :---: |
|  | A-D. je 1,5 bp <br> E. 3 bp <br> G: 2 bp |
| 5.2 | Draw "arrows" in the structural formula of D , which make the formation of E plausible. |
|  | (see above) 0,5 bp |
| 5.3 | Draw "arrows" in the structural formula of $\mathbf{E}$, which make the formation of $F$ (given) from reactant $\boldsymbol{E}$ plausible. Name the given reaction type in as much detail as possible. What is the name of this reaction? |
|  | See above; [4+2]-Cycloaddition (Diels-Alder-Reaktion) 1bp |
|  | Write down the function of $K O^{t} B u$ in the reaction $C \rightarrow D$. Name the mechanism according to which this reaction proceeds. |
|  | Base-induced elimination following an E2 kinetic 1bp |
| 5.5 | State the reason why the mesyl group was introduced into the structure of $A$. Write down a maximum of one sentence about it! |

Since $\mathrm{OH}^{-}$is a bad leaving group, the introduction of the mesyl-group is a better, less nucleophilic leaving group for the elimination from $\mathbf{C}$ to $\mathbf{D}$. The mesyl-group inhibits the esterification of the OH with acyl chlorid.

Full points for one reason 1,5 b

## B. Synthesis of $\beta$-trans-Bergamotes ( $13,5 \mathrm{bp}$ )

(Corey, E. J. Desai, M.C. Tet. Lett. 1985, 26, 3535.)
Bergamotes form a group of isomeric compounds that occur in various plants, especially in essential oils. This task deals with the synthesis of $\beta$-trans-Bergamotes. As a pheromone it acts defensively against the attack of herbivorous insects by attracting natural enemies of these insects.

Hints:
In step E to $\mathrm{Fa}[2+2]$-Cycloaddition with the $\pi$ electrons of the ketene and a $\mathrm{C}=\mathrm{C}$ double bond takes place. That results in a derivative of the bicycle „Bicyclo[3.1.1]heptane". Substance F shows an intense IR absorption at $1710 \mathrm{~cm}^{-1}$, substance $G$ does not.
5.6 Suggest one reagent $\boldsymbol{a}$ and one reagent $\boldsymbol{b}$ for reaction 1 or 2 in the upper reaction scheme.
a: $\mathrm{CH}_{3} \mathrm{Br} \quad$ b: NaH or nBu-Li (strong, weak nucleophilic base)
1 bp
5.7 Specify the reaction mechanism according to which reaction 1 in the upper reaction scheme proceeds.

| $\mathrm{S}_{\mathrm{N}} 2$ |  | 0,5 bp |
| :---: | :---: | :---: |
| 5.8 Draw the resonance structure of the product of reaction 2 in the upper reaction scheme, representing the Ylide. |  |  |
| $\mathrm{Ph}_{3}-\mathrm{P}=\mathrm{CH}_{2} \longleftrightarrow \mathrm{Ph}_{3}-\stackrel{+}{-}-\mathrm{CH}_{2}$ |  |  |
|  | Suggest one suitable and one unsuitable solvent for reaction 2 in the above reaction scheme. |  |
|  | suitable: THF (aprotic) |  |

unsuitable: EtOH (protic) 1 bp
5.10 Draw the constitutional formulae of substances $A, B, C, D$, and the structural formulae of $F$ and $G$ in the correct conformation (no planar rings!)

## C. Synthesis of Aspidospermin ( 25 bp )

(Stork, G.; Dolfini, J.E. J. Am. Chem. Soc. 1963, 85, 2872-2873.)
This task involves the synthesis of aspidospermine, a monoterpenoid indole alkaloid. Aspidospermine is one of over 100 known aspidosperm alkaloids and was first isolated from the quebracho tree, which is native to Chile.

### 5.11 Draw the structural formulae of butanal, $\boldsymbol{A}$ - , and $\boldsymbol{Z}$ (11 pieces), taking into account the correct stereochemistry.

|  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Butanal: 0,5 bp A: 1,5 bp H: 1,5 bp | $\begin{aligned} & \text { B: } 2 \mathbf{b p} \\ & \text { I: } 2 \text { bp } \end{aligned}$ | $\begin{aligned} & \text { C: } 1 \text { bp } \\ & \text { J: } 3 \text { bp } \end{aligned}$ | $\begin{aligned} & \text { D: } \mathbf{2} \mathbf{b p} \\ & \text { K: } \mathbf{2} \mathbf{b p} \\ & \hline \end{aligned}$ | $\begin{aligned} & \text { E: } 3 \text { bp } \\ & \text { Z: } 1 \mathbf{b p} \end{aligned}$ | F: 1,5 bp | G: 2 bp |
| 5.12 Name the mechanism by which K is formed from J. |  |  |  |  |  |  |
| $\mathrm{A}_{\mathrm{N}}\left(+\right.$ elimination of $\left.\mathrm{H}_{2} \mathrm{O}\right)$ |  |  |  |  |  |  |
| 5.13 Determine the absolute configurations of the stereogenic centers 2-4 in the product Aspidospermine. Write only $2=\ldots ; 3=\ldots$ etc., do not draw the structure of aspidospermine! |  |  |  |  |  |  |
| $2=\mathrm{R} ; 3=\mathrm{R} ; 4=\mathrm{R}$ |  |  |  |  |  |  |

## D. Synthesis of Prostaglandin-Fragments (10 bp)

(Corey, E. J.; Ensley, H.E. J. Am. Chem. Soc. 1975, 97, 6908.)
Prostaglandins are derivatives of eicosan and act as tissue hormones in the animal and human organism. They play an essential role in an inflammatory reaction, a form of nonspecific immune defense. This problem involves the synthesis of a special prostaglandin fragment.

5.14 Draw the structural formulae of $A, B$, and $C$, taking into account the correct stereochemistry.

| base - deprotonation of - COOH | $\mathbf{0 , 5} \mathbf{~ b p}$ |
| :--- | :--- |
| 5.16 <br> Write down the cyclic intermediate that leads to the formation of $C$ and draw "arrows" <br> that make the opening of the cycle with the formation of C plausible. |  |
| (see above) | $\mathbf{2 ~ b p}$ |
| 5.17 <br> Name the mechanism by which the reaction to substance A proceeds and name the <br> function of LiAlH |  |
| Reduction of the ester group, $\mathrm{A}_{\mathrm{N}}$ |  | $\mathbf{1 ~ b p}$.

## E. At the organic end it becomes purely pericyclic (9 bp)

In the following problems, remember the Woodward Hoffmann rules and the terms con- and disrotatory.

5.18 Draw the structural formulas of $A$ and $B$, taking into account the correct stereochemistry.

## B: 1,5 bp

A: 1,5 bp

[^1]

## Structural elucidation of oriental spices

The history of herbs and spices goes back almost to the beginning of humankind. Among other things, caraway seeds have been found in the remains of the Neolithic ( $3,000 \mathrm{BC}$ ) lakeside settlements in Switzerland. In 2300 BC, an Egyptian tablet shows the use of cassia and thyme in beer production. Around 700 BC , a cuneiform script library of the Assyrian ruler Assurbanipal describes dill, fennel, cardamom, saffron, sesame, and thyme. Thus the following pages of the competition take their place in the ancient cultural history of the description of spices. Of course, we will not use hieroglyphics or cuneiform script to decipher the information.

## A. Caraway

The main components of caraway seeds are $D$-(+)-Carvone (over 50\%), $D$-(+)-Limonene (over $30 \%$ ), myrcene und $\alpha$-phellandrene. $D$-(+)-Carvone is (S)-2-Methyl-5-(prop-1-en-2-yl)-cyclohex-2-enone.

### 6.1 Draw the structural formula of D-(+)-Carvone and mark the stereogenic center with an *.

(5S)-5-isopropenyl-2-methyl-cyclohex-2-en-1-one

The table indicates some properties that can be measured on substances

|  | Property |
| :---: | :--- |
| $A$ | Boiling point |
| $B$ | UV spectrum |
| $C$ | Refractive Index |
| $D$ | Melting point |
| $E$ | Optical rotation |
| $F$ | Dipole moment |
| $G$ | NMR spectrum in an achiral environment |
| $H$ | IR spectrum |

6.2 Specify the letters of all properties that can be used to distinguish between D-(+)Carvone and L-(-)-Carvone.
E
$\alpha$-Phellandrene
${ }^{1} \mathrm{H}$-NMR Spektrum ( $500 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ):
$\delta($ in ppm$)=6.14(\mathrm{~d}, \mathrm{~J}=10.4,1.0 \mathrm{~Hz}, 1 \mathrm{H}), 5.78-5.91(\mathrm{~m}, 2 \mathrm{H})$, $1.95-2.10(\mathrm{~m}, 2 \mathrm{H}), 1.80-1.91(\mathrm{~m}, 1 \mathrm{H}), 1.63-1.76(\mathrm{~m}, 4 \mathrm{H})$, 0.84 (dd, J = 6.2, $1.5 \mathrm{~Hz}, 6 \mathrm{H}$ ).

$\alpha$-Phellandrene

Besides the $\alpha$ phellandrene, there exists the isomer $\beta$ phellandrene.
$\beta$-Phellandrene

### 6.5 Specify the total number of stereoisomers of both phellandrene molecules mentioned. <br> Total number: $2^{2}=4$, two pairs of enantiomers ( $\alpha$-Phellandren: R/S and $\beta$-Phellandren: R/S)

## B. Thyme

The main components of the essential oil of thyme are thymol (25-50\%), carvacrol (a constitutional isomer of thymol, 3-10\%), and p-cymene. Here we will take a closer look at two other constituents of thyme oil, let us call them $A$ and $B$. The isomers $A$ and $B$ have the molecular formula $\mathrm{C}_{10} \mathrm{H}_{18} \mathrm{O}$.
Substance A is bicyclic; it is 1,7,7-Trimethyl-bicyclo[2.2.1]heptan-2-ol. In the bicyclic nomenclature, bridgehead C is given number 1, followed by bridges starting with the longest and ending with the shortest.

[^2](

Three IR spectra of bicyclic compounds are given below.

| 6.7 | Which of the three IR spectra listed belongs to substance A? Enter the name given (IR- |
| :--- | :--- |
| 1, IR-2, or IR-3). |  |
| IR-1 | $\mathbf{1 b p}$ |

IR-1

IR-2

IR-3

${ }^{1} \mathrm{H}$ - and ${ }^{13} \mathrm{C}$-NMR and IR spectra of substance B are given (see next page). If the ozonolysis of B is carried out with oxidative processing, three products are obtained: Acetone (propanone), X , and $\mathrm{Y} . \mathrm{p}$

The elemental analysis of Y yields $44.44 \% \mathrm{C}, 6.23 \% \mathrm{H}$, and $49.33 \% \mathrm{O}(\mathrm{m} / \mathrm{m})$. The following ${ }^{1} \mathrm{H}$-NMR spectrum (in DMSO-d6 as solvent) was also recorded from Y:

| 6.8 | Specify the formulas of $X$ and $Y$. |  |
| :--- | :--- | :--- |
| $\mathrm{X}: \mathrm{CH}_{2} \mathrm{O}_{2}$ | $\mathrm{Y}: \mathrm{C}_{6} \mathrm{H}_{10} \mathrm{O}_{5}$ | $\mathbf{2 ~ b p}$ |

6.9 Draw a constitutional formula of $Y$.

6.10 Draw a constitutional formula of substance B.

## Spectra of substance B:

## IR-Spektrum:

## Problem 7 (G. Schellander)

## Thermo- and quantum-chemical consideration of some $B, P$, and $N$ compounds

## Borazine

The Lewis acid $\mathrm{BH}_{3}$ reacts with the Lewis base $\mathrm{NH}_{3}$ to form the aminoborane $\mathrm{H}_{3} \mathrm{~B}-\mathrm{NH}_{3}$. Organic-oriented people immediately think of the isoelectronic ethane $\mathrm{H}_{3} \mathrm{C}-\mathrm{CH}_{3}$. Hoping for further parallels to carbon chemistry, they are not disappointed. Borazine $\mathrm{B}_{3} \mathrm{~N}_{3} \mathrm{H}_{6}$ with its hexagonal backbone is also called inorganic benzene.
7.1 For borazine, draw three resonance structures with all electron pairs and any formal charges. Also use mesomeric limiting formulas that suggest the aromaticity of the structure.

(1bp withdrawn for missing formal charges, missing ion pairs, missing aromaticity) 3 bp
The internal angles in Borazine are not quite the same, as the following sketch shows and as the correct Lewis formula suggests:

### 7.2 Write the correct element symbols (N or B) for $X$ and $Y$. <br> $\mathrm{X}=\mathrm{N}, \mathrm{Y}=\mathrm{B}$ <br> $1,5 \mathrm{bp}$

## Boron Nitride

A further interesting compound is the boron nitride BN. It exists - like carbon itself - in several modifications. The graphite-analogous hexagonal $\mathrm{BN}(\mathrm{h}-\mathrm{BN})$ is formed in a reaction of boric acid $\mathrm{H}_{3} \mathrm{BO}_{3}\left(\right.$ or $\left.\mathrm{B}(\mathrm{OH})_{3}\right)$ and urea $\mathrm{CO}\left(\mathrm{NH}_{2}\right)_{2}$, among others:

Reaction 1:

$$
2 \mathrm{~B}(\mathrm{OH})_{3(\mathrm{~s})}+\mathrm{CO}\left(\mathrm{NH}_{2}\right)_{2(\mathrm{~s})} \rightarrow 2 \mathrm{BN}_{(\mathrm{s})}+\mathrm{CO}_{2(\mathrm{~g})}+5 \mathrm{H}_{2} \mathrm{O}_{(\mathrm{g})}
$$

Four reactions (based on boron trioxide or ammonium carbamate) and their reaction enthalpies are given at 298 K :

| (A): | $\mathrm{B}_{2} \mathrm{O}_{3(\mathrm{~s})}+2 \mathrm{NH}_{3(\mathrm{~g})} \rightarrow 2 \mathrm{BN}_{(\mathrm{s})}+3 \mathrm{H}_{2} \mathrm{O}_{(\mathrm{g})}$ | $\Delta_{\mathrm{R}} H^{\ominus}=131,1 \mathrm{~kJ} / \mathrm{mol}$ |
| :--- | :--- | :--- |
| (B): | $\mathrm{B}_{2} \mathrm{O}_{3(\mathrm{~s})}+3 \mathrm{H}_{2} \mathrm{O}(\mathrm{g}) \rightarrow 2 \mathrm{~B}(\mathrm{OH})_{3(\mathrm{~s})}$ | $\Delta_{\mathrm{R}} H^{\ominus}=-189,7 \mathrm{~kJ} / \mathrm{mol}$ |
| (C): | $\mathrm{H}_{2} \mathrm{NCOONH}_{4(\mathrm{~s})} \rightarrow 2 \mathrm{NH}_{3(\mathrm{~g})}+\mathrm{CO}_{2(\mathrm{~g})}$ | $\Delta_{\mathrm{R}} H^{\ominus}=157,2 \mathrm{~kJ} / \mathrm{mol}$ |
| (D): | $\mathrm{H}_{2} \mathrm{NCOONH}_{4(\mathrm{~s})} \rightarrow \mathrm{CO}\left(\mathrm{NH}_{2}\right)_{2(\mathrm{~s})}+\mathrm{H}_{2} \mathrm{O}_{(\mathrm{g})}$ | $\Delta_{\mathrm{R}} H^{\ominus}=67,6 \mathrm{~kJ} / \mathrm{mol}$ |

7.3 Calculate the value $\Delta_{R} H_{298}^{\ominus}$ for reaction 1 using the given data. Show how you include reactions (A) to (D) in the calculations.

$$
\begin{array}{lc}
-(\mathrm{A})+(\mathrm{B})-(\mathrm{C})+(\mathrm{D})+\text { reaction } 1=0 & \mathbf{1 , 5} \mathbf{~ b p} \\
-131,1-189,7-157,2+67,6+\Delta_{\mathrm{R}} H^{\ominus} \text { (reaction 1) }=0 & \\
\Rightarrow \Delta_{\mathrm{R}} H^{\ominus}=410,4 \mathrm{~kJ} / \mathrm{mol} & \mathbf{1} \mathbf{~ b p}
\end{array}
$$

In reality, reaction 1 takes place at temperatures significantly higher than $25^{\circ} \mathrm{C}$. Here are the isobaric heat capacities:

| Compound | $C_{\mathrm{p}} / \mathrm{Jmol}^{-1} \mathrm{~K}^{-1}$ |
| :--- | :---: |
| $\mathrm{BH}_{3} \mathrm{O}_{3(\mathrm{~s})}$ | 86,1 |
| $\mathrm{BN}_{(\mathrm{s})}$ | 19,7 |
| $\mathrm{CH}_{4} \mathrm{~N}_{2} \mathrm{O}_{(\mathrm{s})}$ | 94,0 |
| $\mathrm{CO}_{2(\mathrm{~g})}$ | 37,1 |
| $\mathrm{H}_{2} \mathrm{O}_{(\mathrm{g})}$ | 33,6 |

7.4 Calculate $\Delta_{R} H^{\ominus}$ for reaction 1 at $900^{\circ} \mathrm{C}$.
$\Delta_{\mathrm{R}} C_{\mathrm{p}}=2 \cdot 19,7+37,1+5 \cdot 33,6-2 \cdot 86,1-94=-21,7 \mathrm{Jmol}^{-1} \mathrm{~K}^{-1}$
1 bp
$900^{\circ} \mathrm{C}=1173,15 \mathrm{~K}(-0,5 \mathrm{bp}$ if this conversion is omitted $)$
$\Delta_{\mathrm{R}} H^{\ominus}{ }_{1173}=\Delta_{\mathrm{R}} H^{\ominus}{ }_{298}+\Delta_{\mathrm{R}} C_{\mathrm{p}}(1173,15-298)$
$=410,4 \cdot 10^{3}-18991=391,4 \mathrm{~kJ} / \mathrm{mol}$
$1,5 \mathrm{bp}$
Graphene as a "single graphite layer" is well known. Single BN layers are also being investigated. There are similarities, but also differences. The figure below shows the structure of such a layer. The B-N bond distance is $1,45 \AA$.

Let us take a look on the $\pi$ electrons in a square section of an infinitely large imaginary layer. That means that we do not have to take phenomena at the edges into account.
7.5 Calculate the number of $\pi$ electrons in a square section with side length $L=300 \AA$ and the number $N$ of electronic states. Round $N$ to a whole number.
If you get no result here, calculate with $N=2500$ states.
Fläche eines Sechsecks: $A=\frac{3 \sqrt{3}}{2} a^{2}=5,4625 \AA^{2}(\mathrm{a}=\mathrm{BN}-\mathrm{Abstand})$
Anzahl der $\pi-\mathrm{e}^{-}=$Anzahl der Ringe im Ausschnitt mal 2 Elektronen Pro Ring 1 bp
$\frac{9 \cdot 10^{4} \AA^{2}}{5,4625 \AA^{2}} \cdot 2=16476 \cdot 2=32952$
Anzahl der Zustände $=$ Anzahl e/ $2 \Rightarrow N=16476$
1 bp
Let us approach the description of these $\pi$ electrons in the model of free electron gas (where the mutual repulsion is neglected), describing them as independent particles in a square twodimensional box potential.

For these electrons, the Schrödinger equation provides the following energy levels:

$$
\begin{equation*}
E_{n_{x}, n_{y}}=\frac{h^{2}}{8 m_{e} L^{2}}\left(n_{x}^{2}+n_{y}^{2}\right) \tag{1}
\end{equation*}
$$

$$
\begin{array}{|ll}
\hline \text { 7.6 } & \text { Arrange the first } 11 \text { energy levels of a square box potential } E_{n_{x} n_{y}} \text { in order of increasing } \\
\text { energy. Start at } E_{11} \text {, end at } E_{33 .} \text {. If two energy levels are degenerate, insert }=\text { in between } \\
\text { (e.g. } E_{51}=E_{78} \text { ) } \\
\hline & E_{11}<E_{21}=E_{12}<E_{22}<E_{31}=E_{13}<E_{32}=E_{23}<E_{41}=E_{14}<E_{33} \\
\hline
\end{array}
$$

Now we are dealing with a very, very large number of states that are close together. The states are occupied up to the so-called Fermi energy $E_{\mathrm{F}}$, states above this are empty. We want to neglect the zero-point energy here, so we set $E_{11} \approx 0$.
For the states we use a graphical representation in an abstract state plane. Its points provide all combinations of quantum numbers and thus represent all possible states:

All states within the radius $R$ are occupied. The number of occupied states thus corresponds to the area of the quarter circle shown. Besides the circle equation: $R^{2}=n_{x}^{2}+n_{y}^{2}$
7.7 Using equation (1) express $R^{2}$ as a function of Fermi energy.
$R^{2}=n_{x}^{2}+n_{y}^{2}=\frac{8 m_{e} L^{2}}{h^{2}} E_{F} \quad 1,5 \mathbf{b p}$
for $E_{F}=\frac{h^{2}}{8 m_{e} L^{2}} R^{2} 0,5 \mathrm{bp}$

### 7.8 Calculate the Fermi energy.

The area of the quarter circle is equal to the number of calculated states.

$$
\frac{R^{2} \pi}{4}=N
$$

Insert and calculate:
$\frac{8 m_{e} L^{2} E_{F} \pi}{4 h^{2}}=N \Rightarrow E_{F}=\frac{N h^{2}}{2 m_{e} L^{2} \pi}=1,404 \cdot 10^{-18} \mathrm{~J}$

While in graphene the electrons are distributed quite evenly, they are not so in BN, as a look at the density distribution of the negative charge shows.

1 bp

## Phosphornitrid

Phosphorus and nitrogen form various compounds. The simplest binary compound is the phosphorus mononitride PN, sometimes also called nitridophosphane - in a way an analog to $\mathrm{N}_{2}$.

| 7.10 Draw the Lewis formula of PN. Is it isoelectronic with $N_{2}$ ? (yes/no) |  |
| :--- | :--- |
| not isoelectronic; |  |
| (0bp when only Lewis formula is drawn) |  |

Two MO diagrams are shown. One of them belongs to the PN. For the questions below, the MOs are simply numbered from the lowest drawn one - which does not have to be the lowest one of the molecule.

### 7.11 Indicate which MO diagram belongs to the PN by writing the correct letter.

(A)

Tip: Draw the correct MO diagram for the following questions and fill it with the correct number of valence electrons.

| 7.12 Indicate the number $(s)$ of degenerate MO-s in diagram $(B)$. |  |
| :--- | :---: |
| 3 and 5 | $\mathbf{0 , 5} \mathbf{~ b p}$ |
| 7.13 Which MO of PN represents an antibonding $\pi$ MO? |  |
| 5 | $\mathbf{0 , 5} \mathbf{~ b p}$ |
| 7.14 Specify the magnetic behaviour of PN (diamagnetic/paramagnetic) |  |
| diamagnetic |  |
| 7.15 Enter the number of the HOMO ofPN. | $\mathbf{0 , 5} \mathbf{~ b p}$ |
| 4 | $\mathbf{0 , 5} \mathbf{~ b p}$ |
| 7.16 Specify the bond order of PN. | $\mathbf{0 , 5} \mathbf{~ b p}$ |
| 3 |  |

The following orbital images show calculated MO-s of PN.

(1)

(2)

(3)

(4)
7.17 For each MO depicted, indicate whether it is a $\sigma$ or $\pi-M O$ and whether it is bonding or antibonding. For example, write "(5) $\sigma$, antibonding".
(1) $\pi$, antibonding; (2) $\sigma$, antibonding; (3) $\pi$, bonding; (4) $\sigma$, bonding $1,5 \mathrm{bp}$
7.18 Arrange the orbitals in order of increasing energy by writing the numbers (1), (2), etc.
$(4)<(2)<(3)<(1)$
1 bp, when two neighboring are switched $\mathbf{2}$ bp
A wavenumber of $\tilde{v}=1390 \mathrm{~cm}^{-1}$ was calculated for the stretching vibration in PN.

$$
\begin{aligned}
& \text { 7.19 Calculate the force constant } k \text { for the PN bond. Use the relative atomic masses of } P \text { and } \\
& \text { N from the PSE. } \\
& k=\omega^{2} \mu=(2 \pi c \tilde{v})^{2} \mu=1098 \mathrm{kgs}^{-2} \\
& \mu=\frac{30,97 \cdot 14,01}{30,97+14,01}=9,6463 u=1,6018 \cdot 10^{-26} \mathrm{~kg}
\end{aligned}
$$

A further PN connection also occurs in several modifications. A section of its grid can be displayed in this way:

| 7.20 Specify the empirical formula of this compound (with the smallest integer coefficients) |  |
| :---: | :---: |
| $\mathrm{P}_{3} \mathrm{~N}_{5}$ | $\mathbf{1 , 5} \mathbf{~ b p}$ |

The Van't Hoff equation makes it possible to determine from equilibrium constants at different temperatures $\Delta_{\mathrm{R}} H \ominus$ and $\Delta_{\mathrm{R}} S \ominus$ by plotting -ln K against $1 / \mathrm{T}$.

| 7.21 From the Van't Hoff equation, give the expression for the slope of this plot and its SI unit. |  |
| :---: | :---: |
| $\Delta_{\mathrm{R}} H^{\ominus} / R \ldots . .$. unit is K (Kelvin) | 1 bp |
| 7.22 From the Van't Hoff equation, give the expression for the $y$-intercept of this plot and its SI unit. |  |
| $-\Delta_{\mathrm{R}} S \ominus / R \ldots .$. no unit (dimensionless) | 1 bp |

For the reaction
Reaction 2: $\quad \mathrm{PH}_{3}{ }_{(\mathrm{g})}+3 \mathrm{Br}_{\text {2 }_{(1)}} \rightarrow \mathrm{PBr}_{3(\mathrm{l})}+3 \mathrm{HBr}_{(\mathrm{g})}$
there's one of those Van't Hoff plots:

| 7.23 Enter the values of the slope and y-intercept from the plot. |  |
| :---: | ---: |
| slope $(-110+20) /(0,0025) \mathrm{K}^{-1}=-36000 \mathrm{~K}$ | $\mathbf{1} \mathbf{~ b p}$ |
| y-intercept: -20 | $\mathbf{0 , 5} \mathbf{~ b p}$ |
| 7.24 Specify $\Delta_{\mathrm{R}} H^{\ominus}$ and $\Delta_{\mathrm{R}} S^{\ominus}$ for reaction 2. |  |
| $\Delta_{\mathrm{R}} H^{\ominus}=-299 \mathrm{~kJ} / \mathrm{mol}$ | $\mathbf{0 , 5} \mathbf{~ b p}$ |
| $\Delta_{\mathrm{R}} S^{\ominus}=166 \mathrm{~J} / \mathrm{Kmol}$ | $\mathbf{0 , 5} \mathbf{~ b p}$ |

Also known are bond dissociation enthalpies $D \ominus_{298}$ in $\mathrm{kJ} / \mathrm{mol}$ :
Br-Br: 193
Br-H: 366
H - P: 297
and Evaporation enthalpies $\Delta_{\text {vap }} H \ominus_{298}$ in $\mathrm{kJ} / \mathrm{mol}$ :
$\begin{array}{llll}\mathrm{Br}_{2}: & 30,9 & \mathrm{PH}_{3}: & 14,6\end{array} \mathrm{PBr}_{3}: 12,9$

```
7.25 Calculate the bond dissociation enthalpy D}\mp@subsup{\ominus}{298(P-Br)}{(P)
    \Delta _ { \mathrm { R } } H = 3 D ( \mathrm { P } - \mathrm { H } ) + 3 D ( \mathrm { Br } - \mathrm { Br } ) + 3 \Delta _ { \text { vap } } H ( \mathrm { Br } _ { 2 } ) - 3 D ( \mathrm { P } - \mathrm { Br } ) - \Delta _ { \text { vap } } H ( \mathrm { PBr } _ { 3 } ) - 3 D ( \mathrm { Br } - \mathrm { H } )
    -299 = 451,8-3 D(P-Br) =
    D Ө298 (P-Br)= 250 kJ/mol
        2,5 bp
```

## Hydrogen - atomic, exotic and molecular

## Atomic hydrogen

In 1888 the Swedish physicist Johannes Rydberg presented the formula for the wavenumbers of the spectral lines in the hydrogen spectrum, which is named after him today:

$$
\begin{equation*}
\tilde{v}=R_{H}\left(\frac{1}{n_{1}^{2}}-\frac{1}{n_{2}^{2}}\right) \tag{1}
\end{equation*}
$$

For hydrogen, the value of the Rydberg constant $R_{\mathrm{H}}=109678 \mathrm{~cm}^{-1}$. The formula gives the ionization energy of the H atom in the ground state correctly ( $13,6 \mathrm{eV}$ ), as well as the wavenumbers or wavelengths of the spectral lines for various series.

A spectral series of the H atom starts at 7459,9 nm and has its shortest wavelength line at 2279,4 nm.

The Rydberg constant can be divided into two parts and thus can be generalized. It is

$$
\begin{equation*}
R_{H}=\frac{\mu_{H}}{m_{e}} R_{\infty}, \quad \text { where } R_{\infty}=\frac{m_{e} e^{4}}{8 \varepsilon_{0}^{2} h^{3} c}=10973732 m^{-1} \tag{2}
\end{equation*}
$$

where $\mu_{H}$ is the reduced mass of the hydrogen atom (one proton and one electron), $m_{\mathrm{e}}$ is the electron mass, and all other natural constants have their usual meaning.
The Schrödinger equation also provides expressions for energy levels of electrons in the hydrogen atom as well as in hydrogen-like ions with the nuclear charge number $Z$ and the reduced mass $\mu$.

$$
\begin{equation*}
E_{n}=-\frac{Z^{2} \mu e^{4}}{32 \pi^{2} \varepsilon_{0}^{2} \hbar^{2} n^{2}} \tag{3}
\end{equation*}
$$

8.4 Show that the Rydberg formula (1) can be obtained from the relation (3) by deriving from (3) the wave number for a transition between the levels $n_{1}$ and $n_{2}$ in hydrogen $(Z=1)$.

$$
E_{2}-E_{1}=\frac{Z^{2} \mu e^{4}}{32 \pi^{2} \varepsilon_{0}^{2} \hbar^{2}}\left(\frac{1}{n_{1}^{2}}-\frac{1}{n_{2}^{2}}\right)=\frac{Z^{2} \mu e^{4} 4 \pi^{2}}{32 \pi^{2} \varepsilon_{0}^{2} h^{2}}\left(\frac{1}{n_{1}^{2}}-\frac{1}{n_{2}^{2}}\right)
$$

for the H -atom $Z=1$ and $\mu=\mu_{H}$
further $\Delta E=h c \tilde{v} \Rightarrow \tilde{v}=\frac{\Delta E}{h c}$
combined:
$\tilde{v}=\frac{\mu_{H} e^{4}}{8 \varepsilon_{0}^{2} h^{3} c}\left(\frac{1}{n_{1}^{2}}-\frac{1}{n_{2}^{2}}\right)=\frac{\mu_{H}}{m_{e}} \cdot \frac{m_{e} e^{4}}{8 \varepsilon_{0}^{2} h^{3} c}\left(\frac{1}{n_{1}^{2}}-\frac{1}{n_{2}^{2}}\right)=R_{H}\left(\frac{1}{n_{1}^{2}}-\frac{1}{n_{2}^{2}}\right) \quad 3 \mathrm{bp}$
8.5 Calculate the Rydberg constant $R_{L i}$ for the Lír-Ion in $\mathrm{cm}^{-1}$. For the mass of the Li atomic nucleus use 6,941 u.

$$
\begin{aligned}
& R_{L i}=\frac{\mu_{L i}}{m_{e}} Z^{2} R_{\infty} \\
& \mu_{L i}=\frac{m_{e} m_{L i}}{m_{e}+m_{L i}}=5,485 \cdot 10^{-4} \mathrm{amu} \approx m_{e} \\
& Z=3, Z^{2}=9 \Rightarrow R_{L i}=9 R_{\infty}=987636 \mathrm{~cm}^{-1}
\end{aligned}
$$

## Exotic hydrogen

In so-called "exotic atoms", individual elementary particles are replaced by others. For example, in muonic hydrogen the muon $\mu\left(m_{\mu}=206,8 m_{e}\right)$ replaces the electron. Both particles are leptons with the same charge, and for this example, we want to disregard the short life of the muon particle (approx. $2,2 \mu \mathrm{~s}$ ).

### 8.6 Calculate the ionization energy of the muonic H atom in $\mathrm{kJ} / \mathrm{mol}$

$$
\mu_{H_{\mu}}=\frac{m_{p} m_{\mu}}{m_{p}+m_{\mu}}=0,10196 u=1,6931 \cdot 10^{-28} \mathrm{~kg}
$$

Energy of ionization $=$ negative energy of ground state $n=1$; use (3):
$E=-E_{n}=\frac{\mu e^{4}}{32 \pi^{2} \varepsilon_{0}^{2} \hbar^{2}}=4,0516 \cdot 10^{-16} \mathrm{~J}$ therefore $243983 \mathrm{~kJ} / \mathrm{mol}$ $3,5 \mathrm{bp}$

The wave function $\Psi_{(1,0,0)}$, i.e., the 1 s orbital, shows a maximum of the radial residence probability at the radius of the first Bohr orbit $a_{0}$. This Bohr radius is usually given as

$$
\begin{equation*}
a_{0}=\frac{4 \pi \varepsilon_{0} \hbar^{2}}{m_{e} e^{2}} \tag{4}
\end{equation*}
$$

Here the atomic nucleus is neglected, otherwise the reduced mass of the system nucleuselectron would have to stand instead of the electron mass.
8.7 Which of the following expressions correctly represents the value corresponding to Bohr's radius for the muonic hydrogen? Write down the letter.
(A) $\frac{4 \pi \varepsilon_{0} \hbar^{2}}{m_{\mu} e^{2}}$
(B) $\frac{4 \pi \varepsilon_{0} m_{p} \hbar^{2}}{m_{\mu} m_{p} e^{2}}+\frac{4 \pi \varepsilon_{0} m_{\mu} \hbar^{2}}{m_{p} m_{\mu} e^{2}}$
(C) $\frac{4 \pi \varepsilon_{0} \hbar^{2}}{\mu_{e} e^{2}}+\frac{4 \pi \varepsilon_{0} \hbar^{2}}{\mu_{p} e^{2}}$
(B)

## Molecular hydrogen

The hydrogen molecule $\mathrm{H}_{2}$ is known to be stable against dissociation which can take place in two ways:
(a) homolytic $\mathrm{H}_{2} \rightarrow \mathrm{H} \cdot+\cdot \mathrm{H}$
(b) heterolytic $\mathrm{H}_{2} \rightarrow \mathrm{H}^{+}+\mathrm{H}^{-}$

The diagram schematically shows the total energy of the system of two H atoms against the nuclear distance $R$. The zero-point of the energy scale corresponds to unbound protons and electrons, so atoms and molecules have the same energy scale. The two curve branches I and II represent the courses for the above-mentioned dissociations.

8.8 Which curve branch stands for which bond splitting? Assign (a) and (b) to the curve branches (I) and (II) correctly.
homolytisch (a) - corresponds to II; heterolytic (b) - corresponds to I $1 \mathbf{b p}$
8.9 Specify the energies required for fissions (a) and (b) in eV. Neglect the zero-point energy of the $\mathrm{H}_{2}$ molecule.
(a) $E=2 \cdot(-13,6)-(-31,9)=4,7 \mathrm{eV}$
(b) $E=17,6 \mathrm{eV}$
$0,5 \mathrm{bp}$
The homolytic cleavage (a) could also take place photolytically, in which case the photon would have to bring along the dissociation energy as minimum energy.
8.10 Does this minimum energy correspond to a minimum wavelength $\lambda_{\text {min }}$ or a maximum wavelength $\lambda_{\max }$ ?

| $\lambda_{\max }$ | $\mathbf{0 , 5} \mathbf{~ b p}$ |
| :---: | :---: |
| 8.11 Calculate this $\lambda$ for the photolysis of $\mathrm{H}_{2}$ in nm. |  |
| $\lambda=\frac{h c}{E}=\frac{6,6261 \cdot 10^{-34} \mathrm{Js} \cdot 2,9979 \cdot 10^{8} \mathrm{~m} / \mathrm{s}}{4,7 \mathrm{eV} \cdot 1,6022 \cdot 10^{-19} \mathrm{~J} / \mathrm{eV}}=264 \mathrm{~nm}$ | $\mathbf{0 , 5} \mathbf{~ b p}$ |
| 8 |  |

8.12 Calculate the electron affinity of the $H$-atom in $\mathrm{kJ} / \mathrm{mol}$ from the available data. Write a positive number if the process $\mathrm{H}+\mathrm{e}^{-} \rightarrow \mathrm{H}^{-}$is exothermic.
Kreisprozess:

| $\mathrm{H}_{2} \rightarrow 2 \mathrm{H}$ | $4,7 \mathrm{eV}$ |
| :--- | :--- |
| $\mathrm{H} \rightarrow \mathrm{H}^{+}+\mathrm{e}^{-}$ | $13,6 \mathrm{eV}$ |
| $\mathrm{H}+\mathrm{e}^{-} \rightarrow \mathrm{H}^{-}$ | $E$ (gesucht) |
| $\mathrm{H}^{+}+\mathrm{H}^{-} \rightarrow \mathrm{H}_{2}$ | $-17,6 \mathrm{eV}$ |
|  | Summe $=0 \Rightarrow E=17,6-4,7-13,6=-0,7 \mathrm{eV}$ |

Elektronenaffinität $=-E=0,7 \mathrm{eV}=68 \mathrm{~kJ} / \mathrm{mol}$ $3,5 \mathrm{bp}$
